I seem to have hit the jackpot with my groups of words - see below. I stopped to mow my lawn and because I was not sure I would not capture some messages twice if I continued - i.e, don't know if putting groups in a bucket and then a dataset walls them off from follow-on searches.

Here is my message to Dr. Shulman, no reply yet. Do you know how to set this up so I can skim a dataset and then code it as if it were one of the exact duplicates?

Message - I have seen how to convert buckets to datasets, and have applied 3 sets of terms so far - Teddy R - 3100; backcountry hunters & Anglers - only 400, as most of those were in the form letters, and awe inspiring monuments, 17,000+. However, I would like to be able to treat these datasets as if they were duplicates, so I only need to review a few to code the entire grouping, and cannot figure that out. Please advise. If we get lucky like this with a few other of these terms will reduce the workload tremendously.
